TITLE: Investigation of the Thermal Behaviour of Intermediate Ladles

PERIODICAL: Izvestiya vysashikh uchebnykh zavodeni. Chernaya metallurgiya, 1960, No. 10, pp. 58 - 66

TEXT: The investigation had been carried out to determine the heat losses from metal in intermediate ladles. Small ladles at the New-Tula Metallurgical Plant and large at the imeni Dzerzhinskiy Plant were studied. The small ladles were heated with blast furnace gas burning in an oxygen jet, and the large with coke gas; chromelalumel and platinumrhodium-platinum thermocouples were inserted into the ladle linings as shown in Fig. 1 and 2; the metal temperature in ladles was measured with platinumrhodium-platinum and tungsten-molybdenum-titanium thermocouples; indicating and recording galvanometers and an 300n -30 (EFP-30) writing potentiometer were used. The duration of teeming was 20 - 20 min at the New Tula Plant (NTMZh) and 60 - 120 min at the imeni Dzerzhinskogo plant. A graph gives the measurement results in a large ladle (Fig. 3) - there is practically no

Investigation of the Thermal Behaviour of Intermediate Ladles

heat gradient inside the intermediate ladle, apparently due to a feed of fresh hot metal from the main ladle. The lining temperature on the surface quickly reached the metal temperature; it dropped nearly 180°C during 5 min after the gas heating was stopped before teeming. E.A. Iodke and L.I. Krupman calculated the heating of lining to determine the effect of separate factors. The "working" layer of lining was stated to be 20 - 30 mm in small ladles, and 60 - 80 mm in large, which is less or equal to the usual fireclay lining depth and shows that additional heat insulation of the ladle casings is superfluous. The calculation is included in the article. The formula (13) determines the effect of the heat conductivity of the ladle lining on the drop in metal temperature in the ladle and shows that the relation is in direct proportion. The heat loss by radiation had not been considered. It was concluded that the heat conductivity in fireclay brick layers nearest to the contact surface with metal drops in the teeming process and the first metal portions in the intermediate ladle are cooled by the lining surface, whilst the heat gradient inside the lining has practically no influence. It is therefore proper to heat the lining at a high temperature on the surface ignoring high temperature gradients in the lining below the surface, and not to stop heating the ladle before the start of teeming. Cooling of the first metal

Title : Unipolar Electrification of Aerosol in the Field of Coronary Discharge

Orig Pub : Vestn. s.-kh. nauki, 1957, No 9, 127-131

Abstract : In treatment of plants with insecticides or other chemicals in the form of aerosols (dusting, spraying), a considerable part of the chemicals is carried away by the wind. The precipitation of the particles is increased by means of their unipolar electrification; the latter is obtained by the passage of aerosol through the field of coronary discharge between the walls of the ground tube and the

TITLE: Hand operated electroaerosol generator and its clinical application

SOURCE: Meditsinskaya promyshlennost' SSSR, no. 9, 1965, 45-9

TOPIC TAGS: medical equipment, aerosol dispenser, electric generator, clinical medicine, charged particle

ABSTRACT: Electroaerosol therapy with aerosol particles of approximately identical electric charge can be easily applied with this generator for individual inhalation, called Electrosol - 1 and developed by VNIIMIO. It works with compressed air at 0.3 atmospheres or more and

Card 1/2

UDC: 615.417.1-032: (615.473.9; 621.313.12)

has a simple pulverizer for dispersing the medication, which is electrically charged in the same operation. The inhalator can be safely turned in any direction and the particles can be positively or negatively charged. The current is 127-220 volts AC. It can also be used for simple inhalation and is easily disassembled for cleaning and sterilization. Clinical application (mostly with negatively charged aerosol) involves daily or every other day inhalations of 5-15 minutes for adults and 3-7 minutes for children. Up to 30 treatments may be given and the course may be repeated after 3-4 weeks. This treatment has been found to have a favorable effect on respiratory organs, blood chemistry and circulation. Antibiotic inhalation obviates the need for repeated injections. The generator may also be used for disinfection and in industry for thin film deposits. This apparatus has been tested, accepted and recommended for commercial production. Orig. art. has: 1 figure.

AUTHOR: B. Kitayev

TITLE: On the Question of Refrigeration of Cargo in Isothermic RR Cars
(K voprosu okhlazhdeniya gruzov v izotermicheskikh vagonakh)

PERIODICAL: Kholodil'naya tekhnika 1959, Nr 2, p 75 (USSR)

ABSTRACT: The article refers to the letter written by M. Ozerov and L. Skorokhodova, published in the Nr 1 issue 1959 of Kholodil'naya tekhnika and containing critical remarks about a certain book dealing with the method of calculating refrigeration of cargo in isothermic RR cars (see Kholodil'naya tekhnika issue Nr 3, 1958). The writer Kitayev states that the theoretical basis of the calculation as developed in the book is correct and that the criticism can concern only the heat exchange of the surface of the cargo. There-

Influence of the Weight of the Charge on the Output of an Open-Hearth Furnace. II. Kileac. (Nat. 1934, No. 7, pp. 21-24) (In Russian). The author gives the formula:

$$f^* = 10.0 - 11.5$$

where I' is the output in tons per day, Q the maximum heat input into the furnace during the introduction of the cold charge in millions of calories per hr., γ the heat (in the same units) which would be lost from the empty furnace, and K the coefficient of utilization of the fuel. This formula was put forward by Semenkin, and it is pointed out that it makes the output independent of the weight of the charge. By further development of the above formula, the author arrives at the following expression:

$$P = \frac{30 - R_0}{R_0}$$

where q_0 is the amount of heat (in millions of calories per hr.) taken up by the charge on introduction into the furnace and T the weight of the charge in tons, and :

$$f' = \frac{150}{25} = 6$$

where σ is the rate of addition of the charge in tons per min. These expressions hold for the process in which scrap and cold pig-iron are used and it is assumed that during each heat there is a period of 1 hr., during which practically no external heat is applied to the charge.

Requirements of a gas for firing an open-hearth furnace
H. Kötter. Aus IN. S. 1, J. No. 36, 27. 01. 1940.
Probabilities are derived for the relation between the efficiency
of an open-hearth furnace and the calorific value and
homogeneity of a gas. The calorific value of cold producer
gas, blast-furnace gas, coke-oven gas, from several kinds of
furnaces, hot producer gas and hot generated gas from pro-
duced fuel is determined. M. Hirsch

Heat exchange in a blast furnace. N. I. Kudryavtsev [N. S.] 6, 202-5(1911). The difference in temp between the gases and the charge within a blast furnace is less at the throat of the furnace than in the cylinder, although the useful vol. of a modern blast furnace is 2-3 times bigger than the calc'd. vol. required for complete heat exchange between the gases and the charge. This is attributed to the fact that the heat exchange proceeds in 2 distinct steps. In the first step, from the throat down, the heat-absorbing power of the gases is greater than that of the charge. As the charge descends the temp difference decreases and the temps. become equal. Farther down the heat-absorbing power of the gases becomes much less than that of the charge because of the absorption of heat by the charge in direct reduction reactions and in melting. At the level of the air nozzles the temp. difference reaches $300-350^{\circ}$ as compared to 200° in the throat. The level at which the temp. of the charge and that of gases commence to diverge is the dividing line between the regions of direct (bottom) and indirect (top) reduction. The temp. at this level corresponds to the temp. at which the rate of reduction of CO_2 by C from the fuel is zero. In furnaces using coke this corresponds to $1320-1400^{\circ}$ and in those using charcoal $1100-1150^{\circ}$. A scheme is outlined for calc's. of the height of the respective zones to a fair degree of approximation. M. Illich

TITLE Slow-motion Moving Pictures Used to Study the Structure of
Flames (Izuchenie strukturny goryashchikh fakelov s pomoshch'-
yu lupy vremeni)

PERIODICAL: Tr. Ural'skogo politekhn. in-ta. 1955, Nr 53, pp 7-21

ABSTRACT: The change with time in the structure of flames was studied through the medium of the slow-motion moving picture, which has the effect of "magnifying" time. The slow-motion film revealed the dependence of flame length on the gas-flow rate and led to several conclusions concerning the diffusion mechanism of gaseous combustion. Bibliography: 6 references.

ABSTRACT: The employment of O₂ and compressed air in the inlet ports, and other measures, tend to increase the turbulence of the flame. The most widely used system of adjusting the fuel-air ratio is that of Koshtyal which, however, does not take into consideration the fact that 1) the amount of CO liberated from the bath may be very high at various periods during the heat; 2) when the rate of emission of the gas, and its heat value, are increased, the excess air does not compensate for the increase in the length of the flame; 3) proportioning is com-

Card 1/2

Requirements for Automatic Control (cont.)

plicated when a furnace is heated by hot generator gas when a viscous carburizer is added. The ratio schedule should be worked out on the basis of an analysis of the combustion products or, better still, directly in terms of the length of the jet of flame. The very low-lag electromagnetic gas analyzer of P. L. Kapitsa, Member of the Academy, may be employed as the primary element. A design employing photoelectric cells should be excited by the temperature of the top of the checkers and should adjust the length of the flame by changing the excess air coefficient. Automatic valve switching should not be employed to eliminate overheating of the roof and the checker-work, because there is a sharp drop in regenerator efficiency if less than 10-20 minutes elapses between switchings. The most practicable method is the one employing switching after the lapse of a set period of time; preservation of the roof and checker brickwork from overheating has to be accomplished by reducing the length of the flame by means of an automatic gas-to-air ratio control device.

TITLE: On the Maximum Size of a Lump of Charge Material in a Blast Furnace (O maksimal'nom razmere kuska shikhty v domennoy pechi)

PERIODICAL: Tr. Ural'skogo politekhn. in-ta, 1958, Nr 73, pp 74-86

ABSTRACT: An attempt is made to obtain a relationship for determining the maximum lump size (LS) of charge material by means of the laws governing the heat exchange and the aerodynamics of the layer. The relationship found indicates that the height of a blast furnace (F) is determined by the LS and that a slight change in LS causes a fairly large change in the height. A change in LS permits the regulation of the temperatures of a blast F by decreasing or increasing the reserve height of the blast F. The author draws the conclusion that an increase in the yield of the blast F obtained through a simultaneous increase in the LS and the height of a blast F results in a deterioration of its volumetric utilization factor.

TITLE: Investigating the charging processes in a voltage-doubler system

PERIODICAL: Izvestiya vuzovskikh uchebnykh zavodov. Tekhnika, no. 3, 1962, 10-16

TEXT: In the event of a periodically varying suppl. voltage or with sharply varying load the charging processes generate harmonics in the valves and overvoltages at the capacitors. A study of the processes is important for the voltage multiplier circuits in high-voltage test plant and feeding radio installations, X-ray equipment, etc. In the case of a Greinacher voltage-doubler circuit not loaded with a capacitor discharge, the output capacity voltage variation in time, during charging, for the general case ($C_1 \neq C_2$) takes the form of a geometric progression. With a constant load-resistance at the voltage-doubler output the mean capacitance charge

voltage and the rate of voltage rise diminish. The general equation describing the charging process expresses both the transient and steady state performance. Equivalent circuits demonstrate characteristics of the doubler circuit such as the capacity charge at the output following an exponential relation, the rate being determined by the $C_1 : C_2$ ratio and the load; the substantial internal resistance, presenting a limit to the charging currents with sharply varying conditions and a descending load curve; and voltage stabilization at the load with supply-voltage fluctuations depending on the relationships of the circuit capacitances. V The structure of extra-thin films of copper hydroxide formed spontaneously on the surface of an aqueous tetraaminocopper solution. N. G. Mokrushin, G. A. Kitayev, and O. K. Shabalina. *Doklady Akad. Nauk S.S.R.* 94, 1109 11(1954).—The structure of $\text{Cu}(\text{OH})_2$ film was studied on the surface of tetraaminocopper soln. formed by placing a drop of the soln. on the cover glass directly over the unadjusted condenser lens of a microscope, and permitting the soln. to vaporize slowly. $\text{Cu}(\text{OH})_2$ was formed hydrolytically and appeared under the microscope as a multitude of brilliant colloidal particles in a lively Brownian movement. An extremely thin film was finally formed on the surface, to which the coarser particles in the suspension adhered. A secondary formation was observed on the cover glass, and it was composed of deposited spherical aggregated particles. Some microscopic pictures of the film are reproduced.

ABSTRACT: Research has been conducted on the kinetics of the growth of cobalt and nickel hydroxide films on the surface of solutions of the corresponding amines with respect to concentration and temperature. The formation of hydroxide films has taken place only in the presence of a monolayer of a surface-active substance on the surface of the solution. The rate of growth of films under a layer of oleic acid has been in-

vestigated. The rate of hydrolysis of the ammines is determined by the rate of ammonia evaporation through the hydroxide film. The following stages are assumed for the formation and growth of cobalt hydroxide films: evaporation of excess ammonia, hydrolysis of cobalt tetrammine with the formation of hydroxide, attachment of the colloidal hydroxide to the surface of the solution. There are 8 graphs, 1 table and 5 Soviet references.

pp.411-415

TEXT: The formation of thin films on the phase boundaries liquid-gas and liquid-solid has been investigated in the authors' laboratory since 1930. In the opinion of the authors, the mechanism of the formation of such films consists of the following stages: formation of a colloidally dispersed substance, adsorption of colloidal particles on the phase boundary and their growth due to coagulation. In the present paper, some experimental data on the kinetics of the formation of copper hydroxide film on the surface of glass submerged in a solution of copper ammoniacate are reported and considered in the light of the above postulated mechanism. The experimental procedure consisted of the immersion of washed glass plates into specially prepared

Card 1/4

An experimental investigation ...

copper ammoniacate solutions for a given time and measuring the thickness of the film formed by interference colours of the reflected light and the concentration of colloidally dispersed hydroxide in the solution by the nephelometric method. The preliminary preparation of copper ammoniacate solutions consisted of the removal of the excess of ammonia by stirring until the appearance of a noticeable opalescence and filtration. It was found that the highest rates of formation of copper hydroxide films takes place at a concentration of $Cu(NH_3)_4SO_4$ from 0.005 to 0.025 mole/litre. The rate of growth of the film increases with increasing opalescence of the solution. If the hydrolysis of copper ammoniacate is prevented (experiments in closed flasks) then the film growth stopped on the attainment of a certain minimum value of opalescence. This fact is considered as proof of the colloidal-chemical nature of the process of formation of the film. By increasing the surface area open to the atmosphere of the vessel in which the experiments were carried out, i.e. by increasing the rate of removal of ammonia, the velocity of growth of the film increases. To describe the process, the authors used an equation derived by M. Smolukhovskiy for the adsorption of a colloidally

Card 2/4

An experimental investigation ...

dissolved substance on a solid surface:

$$M = \frac{2\psi\sqrt{Dt}}{\sqrt{\pi}}$$

where M is the total number of particles adhering to the solid surface at the time t , ψ is the number of particles in 1 cm^3 , D is the coefficient of diffusion. Assuming ψ = constant, $\lg M = K + 0.5 \lg t$. Using this equation and assuming that the thickness of the film Δ is directly proportional to the number of adsorbed particles ($\lg \Delta = K_1 + 0.5 \lg t$), the authors obtained a good agreement between the experimental and calculated results. In the choice of optimal conditions for the process, it is necessary to control the velocity of hydrolysis (i.e., the velocity of formation of sol) and the velocity of coagulation, increasing the former and decreasing the latter. At a high velocity of coagulation (a high concentration of copper ammoniacate and at temperatures above 25°C) the velocity of film growth is low. There are 6 figures and 10 references; 8 Soviet and 2 non-Soviet. The reference to an English language publication reads as follows:

TITLE: Conditions of chemical deposition of thin cadmium sulfide films on a solid surface

SOURCE: Zhurnal fizicheskoy khimii, v. 39, no. 8, 1965, 2065-2066

TOPIC TAGS: cadmium sulfide, thin film, thiourea, thermodynamic calculation

ABSTRACT: The process of deposition of cadmium sulfide films from aqueous solutions (with the use of thiourea as the sulfiding agent) is treated thermodynamically. The treatment consists in a graphical solution of the equations describing the equilibria

The equations

$$\text{pH} = \text{pK}_{\text{H}_2\text{O}} - 1/2 \text{SP} + 1/2 \text{p}[\text{Cd}^{2+}] \quad (1)$$

(where $\text{pK}_{\text{H}_2\text{O}} = 10^{-14}$ is the ion product of water at 25°C and SP is the solubility

ACCESSION NR: AP5021426

product) and

$$4p[NH_3] = pK + p[Cd(NH_3)_4^{2+}] - p[Cd^{2+}] \quad (2)$$

are solved graphically. The graph is used to find the relative concentrations of OH^- and NH_3 , or pH and $p[NH_3]$, at which cadmium hydroxide is formed in the solution. Thus, the thermodynamic method describes the decomposition of thiourea with the evolution of S^2 ions and the resulting formation of cadmium sulfide and its deposition as a mirror film on any solid surface. The method also makes it possible to simplify the system by eliminating the alkali and using only two reagents - the cadmium salt and thiourea. Orig. art. has: 1 figure and 6 formulas.

TITLE: Experimental studies of laminar systems. Part 31. Kinetics and mechanism of formation of cadmium sulfide films on a glass surface

SOURCE: Kolloidnyy zhurnal, v. 27, no. 5, 1965, 767-772

TOPIC TAGS: cadmium sulfide, colloid, chemical reaction kinetics, chemical dispersion

ABSTRACT: The kinetics of formation of colloidally dispersed cadmium sulfide in aqueous alkaline solutions with the use of thiourea were studied between 15 and 45°C in closed vessels, in which thicker films of better quality are obtained than in open vessels. The process was shown to be heterogeneous, autocatalytic, and catalyzed by hydroxyl ions and by the surface of the solid phase dispersed in the solution. The order of the reaction with respect to the alkali, ammonia, and thiourea was determined. The formation, growth, and structure of the cadmium sulfide films depend on the course of generation of primary colloidal particles of the dispersed phase. TOPIC TACS: cadmium sulfide, semiconducting film, chemical deposition, chemical reaction kinetics, optic coating

ABSTRACT: The authors continued their earlier studies of the kinetics and mechanism of the known chemical process of deposition of cadmium sulfide mirror-like films on a glass substrate from the thiourea-containing, aqueous basic solutions. The kinetics of two interrelated processes: accumulation of CdS in the solution and growth of CdS films on the substrate were studied experimentally. Similarity in the mechanism of the two processes was deduced from comparison of their rate constants which were calculated from the earlier established kinetic equations and new experimental data. The kinetic equations which describe the two processes were shown to be identical. Accordingly, both processes involve the same mechanism -- deposition of CdS, a product of a heterogeneous chemical reaction, either on colloidal CdS particles suspended in the
